

# A Model of Extragalactic Foregrounds for Unbiased Estimation of Cosmological Parameters from Planck and Other Ground Based Data

Marius Millea  
Advisor: Lloyd Knox  
UC Davis

For CINC 2010

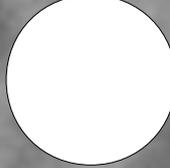

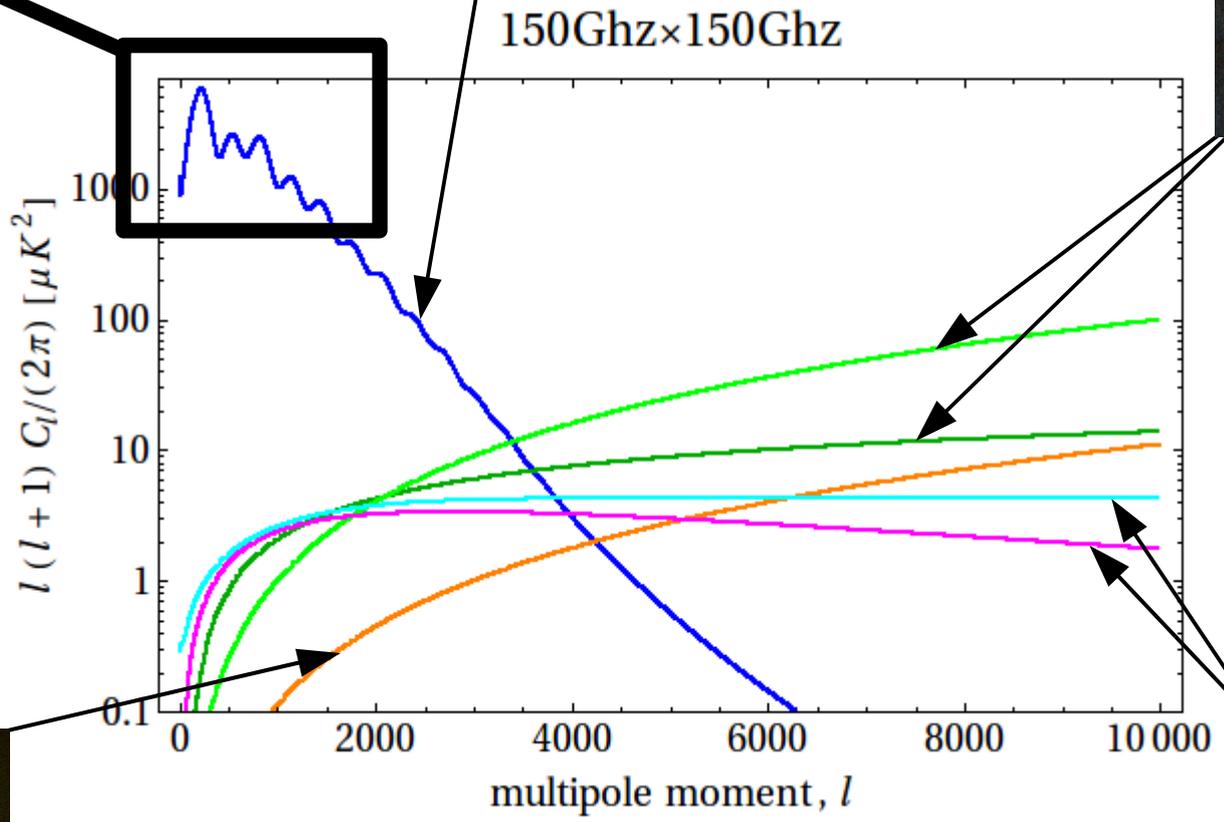

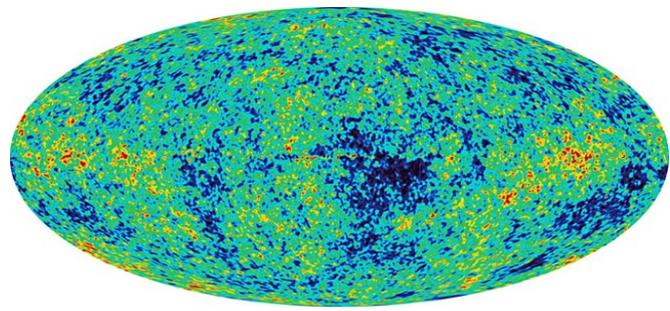

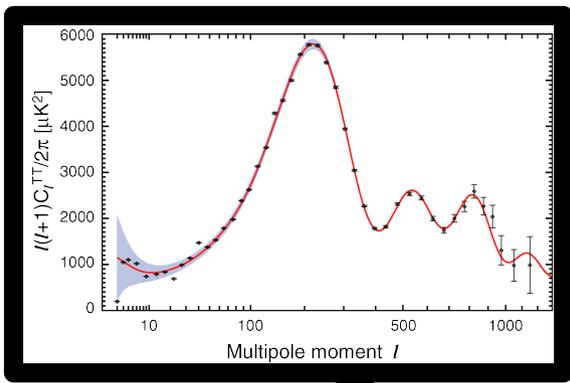

4 deg<sup>2</sup> SPT  
2008 – 23hr field

15 sigma SZ detection

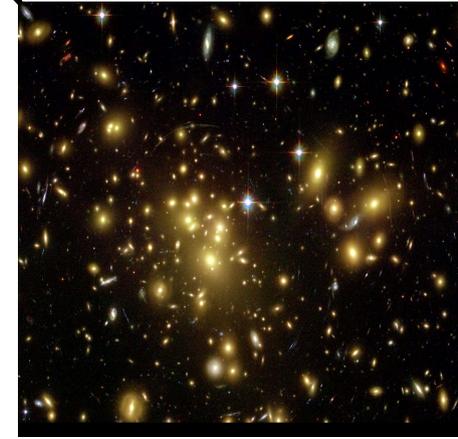

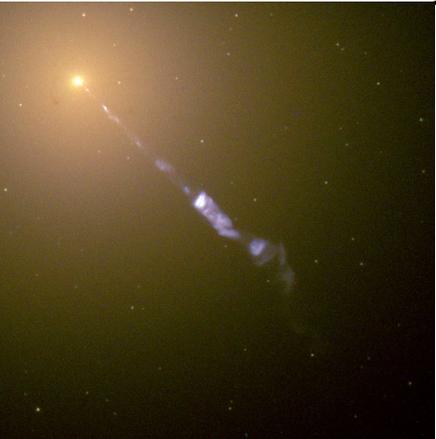

Bright point  
sources

Every pixel has  
some contribution  
from unresolved  
point sources and  
SZ

 SPT @220Ghz  
 Planck @217Ghz  
 WMAP @94Ghz

# Point source frequency dependence

Vieira 2010 catalog

# Typical dusty galaxy spectra

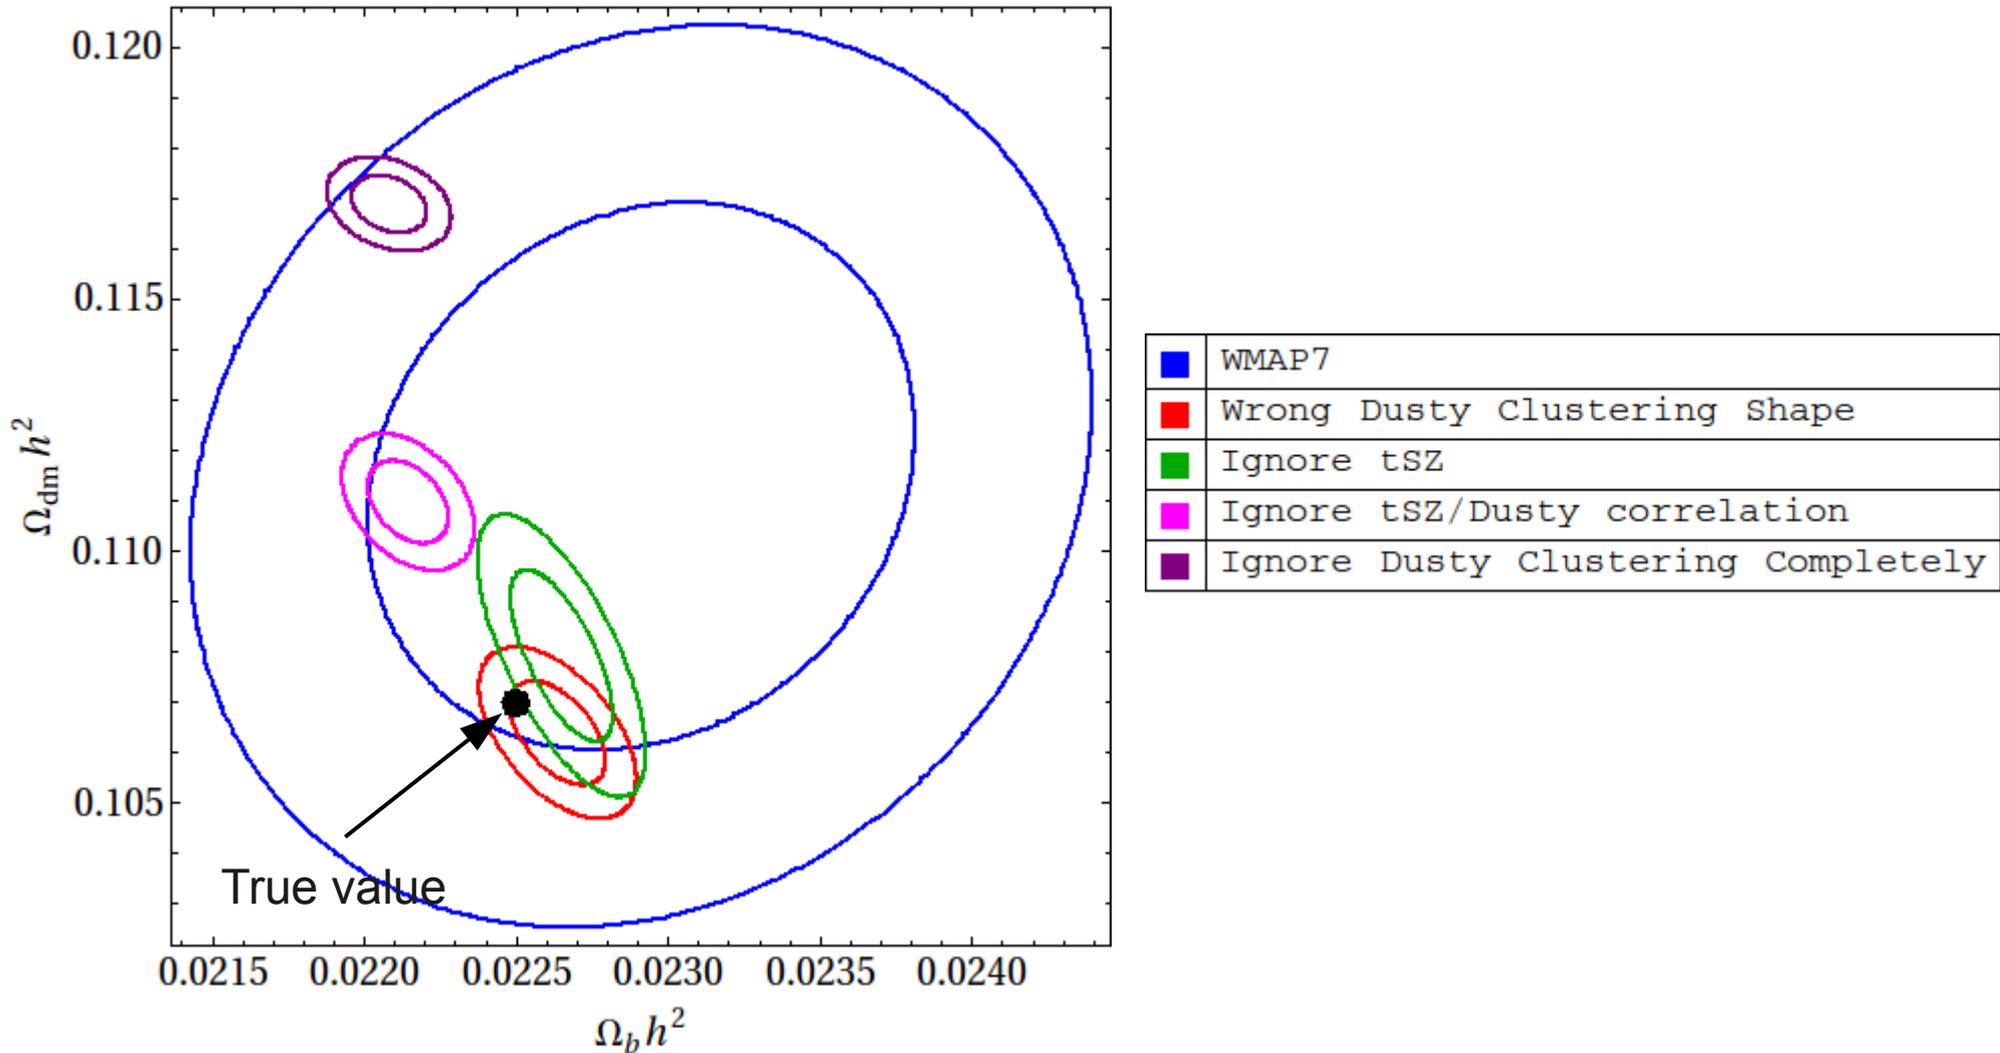

~30K greybody component

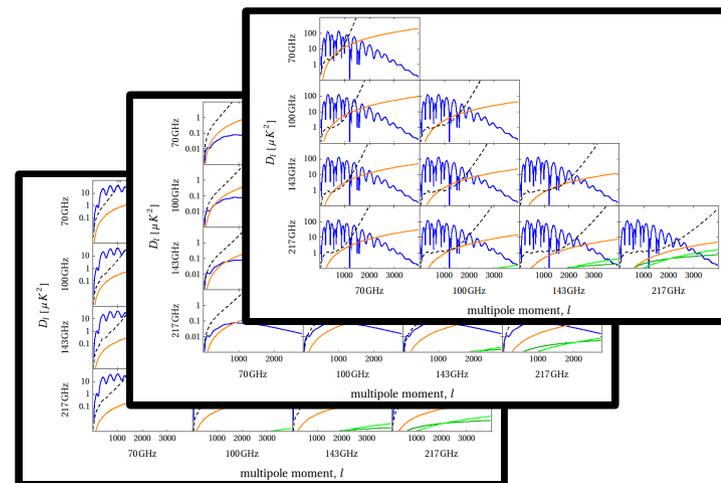

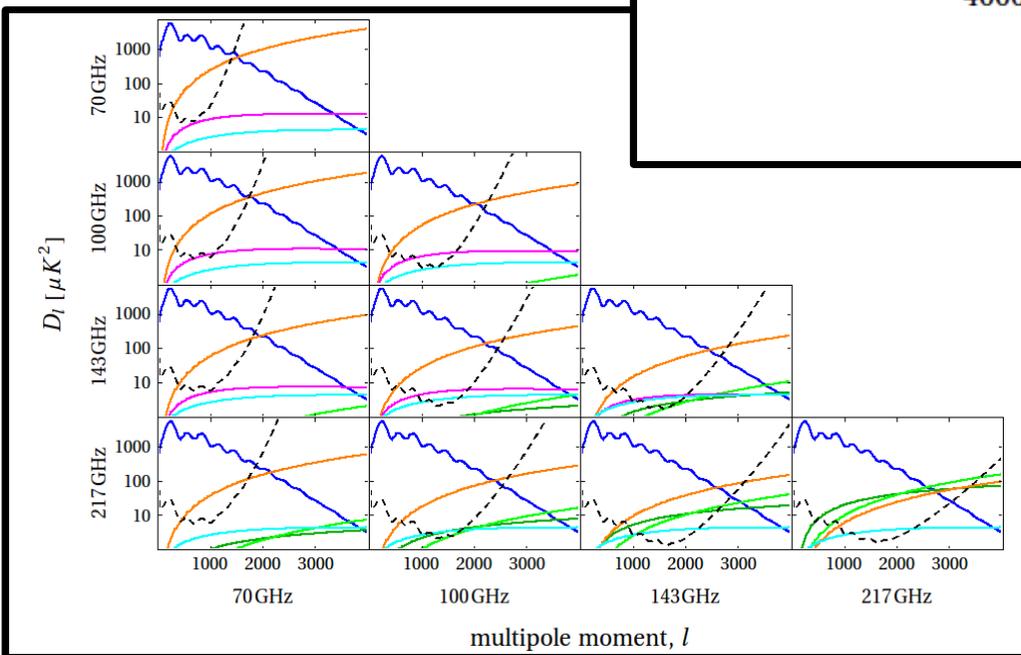

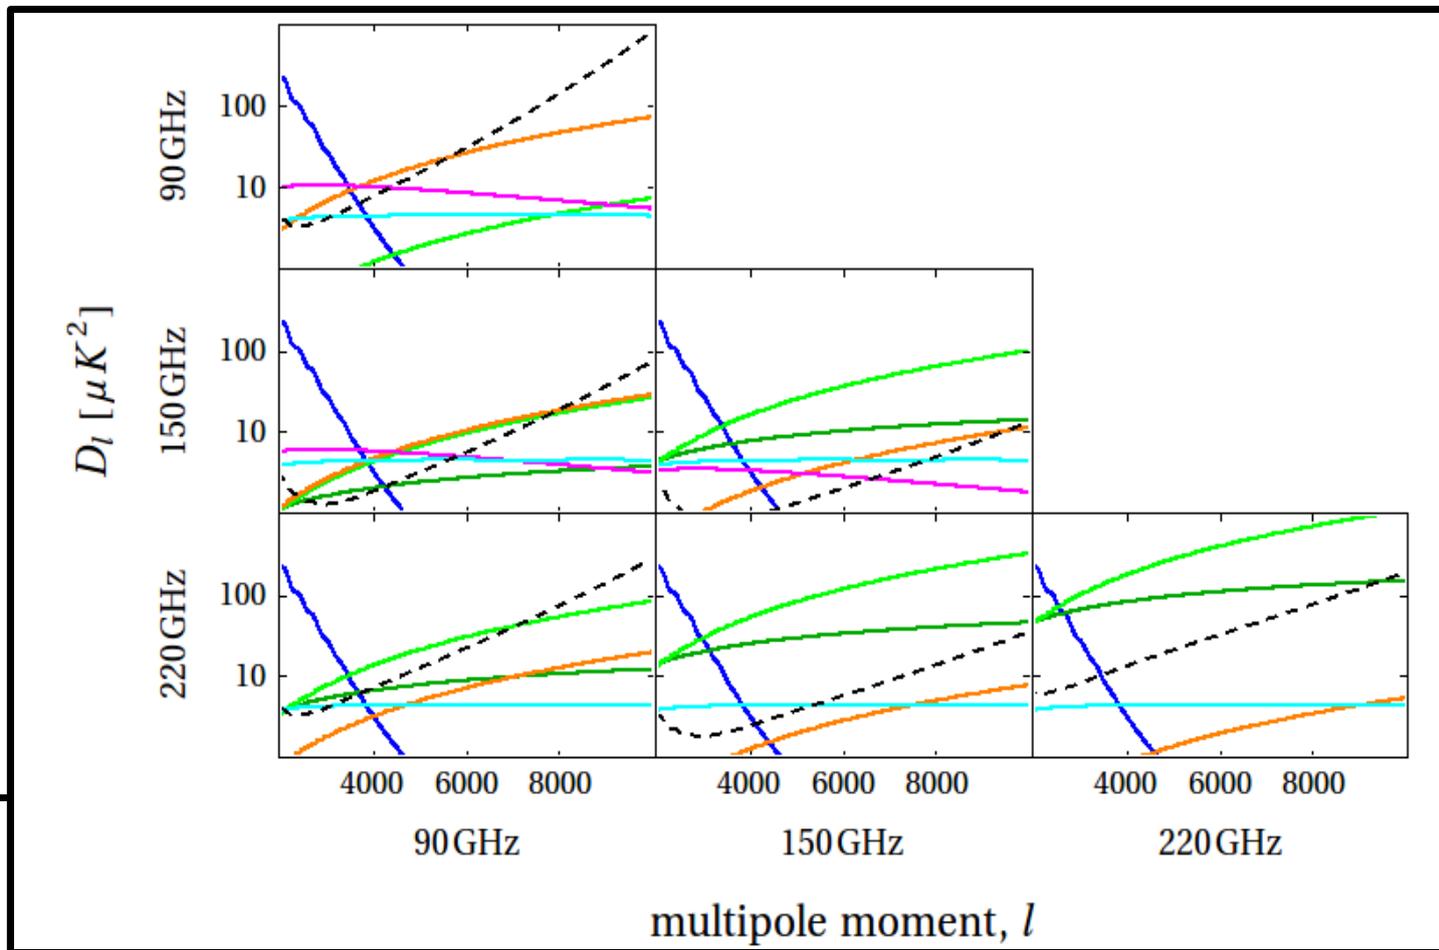

~100-200GHz component

# Results

- Significant biases from neglecting to model one of the components, or even from just getting the details wrong

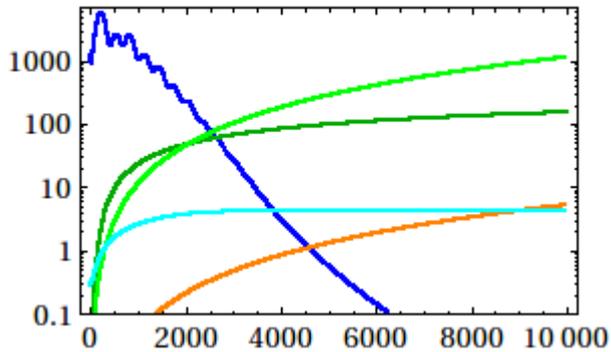

# Adding SPT & Data Reduction

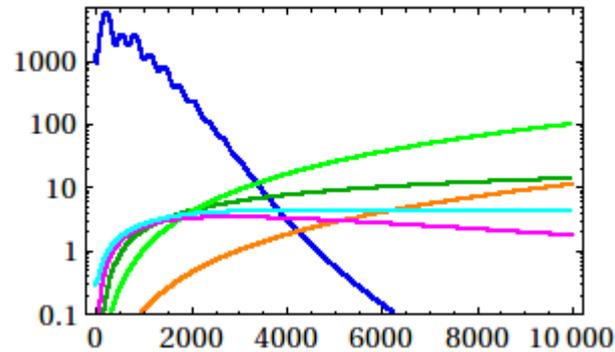

# Intermediate Step

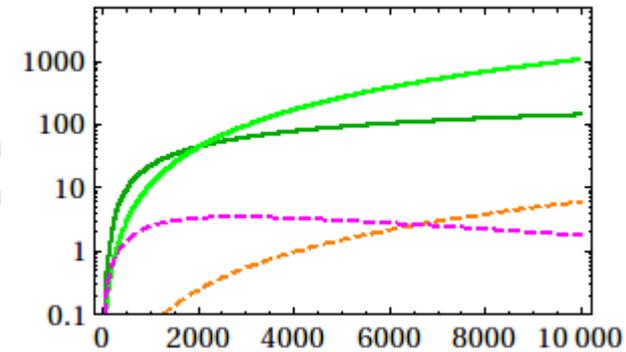

220 GHz × 220 GHz

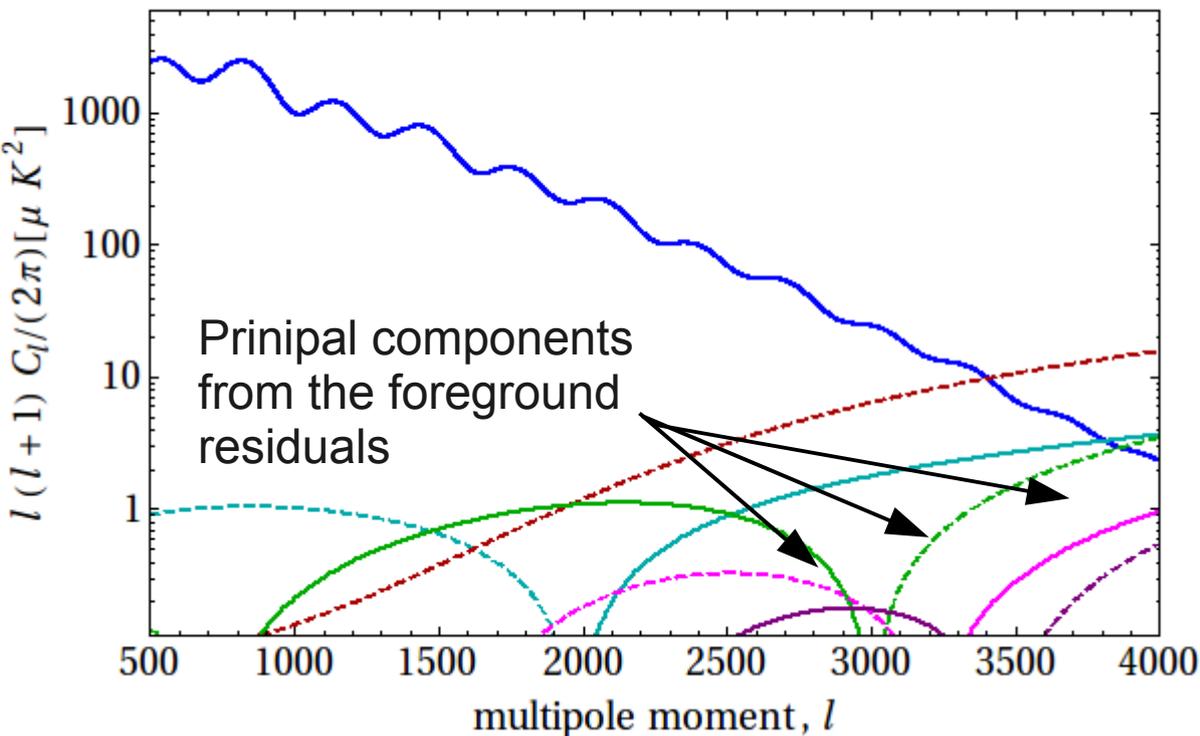

150 GHz × 150 GHz

CMB Free

Reduced CMB

- Create a bunch of CMB free differenced spectra and use them to constrain the foregrounds
- Create an “inverse variance weighted” CMB estimate and subtract the mean foregrounds from step 1.
- Marginalize over residual foregrounds using several PC's

# Conclusion

- We've developed a multifrequency high- $\ell$  foreground model informed by ground based data (e.g. SPT) which can be used to remove foregrounds in Planck.
- Convinced you of the importance of foregrounds.
- We're working on an analysis method which separates the foreground modeling from cosmological parameter estimation.
- Very soon the first year Planck power spectra will be ready, and we're eager to test our model
